1 Memory

1.1 Hexadecimal

Most western cultures use base 10 to represent numbers. Computers on another hand use base 2, otherwise called binary system. In most cases programmers want to understand some aspect of what computer is storing. It becomes hard to read the binary numbers and so therefore, a better method was sought.

Hexadecimal is a base 16 system where number are represented by: **0 1 2 3 4 5 6 7 8 A B C D E F**. This is a compact human friendly way to represent binary digits.

In C programming, pointers are printed in hexadecimal format.

1.2 Pointers

Pointers allows us to get the real data. This is very useful when we are passing data between functions.

A pointer is therefore, a data point whose value is the memory address of a particular variable.

We can have null pointer when we want our pointer to point at nothing.

Finally, another important aspect in pointers, is dereferencing. Dereferencing is basically getting the real data item stored in that particular memory.
